

What have we done so Far?

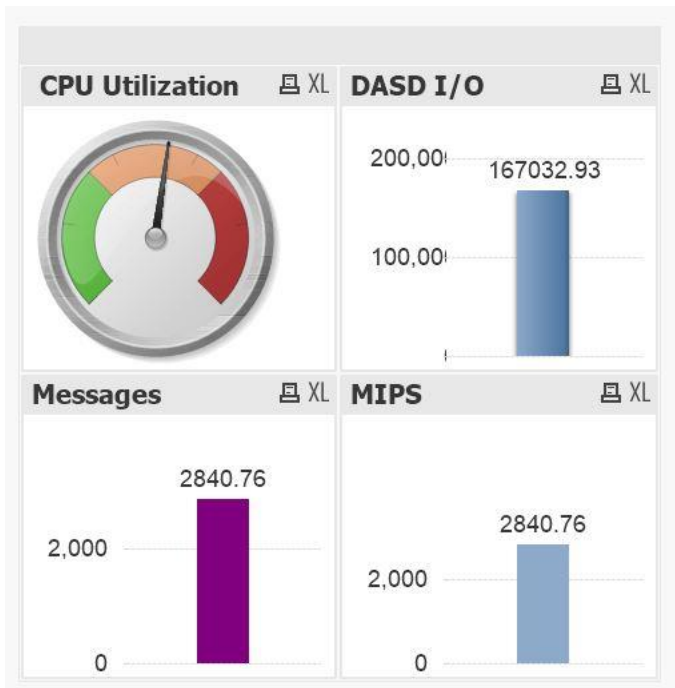

1. SQL Queried these tables from a DB2 database in Qlik View

2. Used these Queried table to make these charts separately

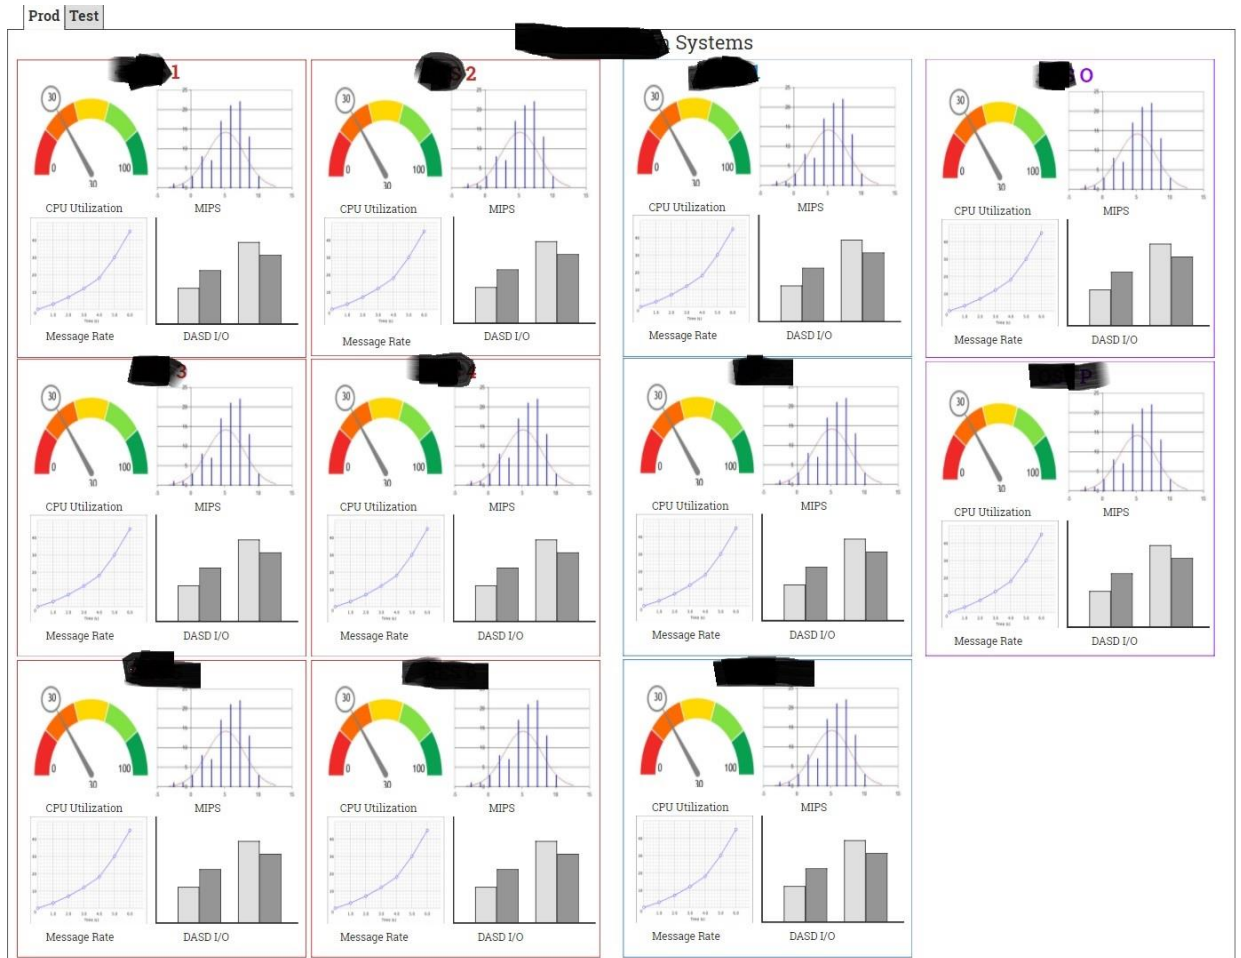

3. Then added these charts in a container because we want these charts as a single widget

What do we need to do now ?

4. I need to build these containers/widgets for various other systems that may range anywhere from 20- 200. And in future these charts may need to be scaled up or down. And ultimately my picture should look something like:

5. Now instead of me building these charts one at a time for large number of systems I would like to write one generic query for all containers. I would pass in the parameters to the container of my interest and parameters I pass will complete the generic query that I have already built. Hence a personalized SQL script would be built for each container to pull the data related to that particular container.
- Is this possible ?
 - How ?
