

I have put together a quick job that I think covers what you want. Hopefully my screenshots will tell the story, but I will add some descriptions where I think more info is needed.

The above is a screenshot of the job. It is split into 3 paths; one for the Machine data, one for the SpeciesGroupDefinition data and one for the ProductDefinition data. This split takes place at the tMap\_1.

The tFileInputXML\_I just receives the XML and outputs an XML Document to the next component. This component is configured as below...

Job Contexts(CommunityJobLoopingXML) Component Run (Job CommunityJobLoopingXML) Test Cases Cloud Artifa

### tFileInputXML\_1

**Basic settings**

Property Type: Built-In 

Schema: Built-In 

File name/Stream:

Loop XPath query:

Mapping

Column	XPath query	<input type="checkbox"/> Get Nodes
xml	"/	

Limit:

Die on error

The next component (tExtractXMLField\_1) is used to extract the "Machine" data and also passes the XML Document untouched to the tMap\_1. This is done by simply including the "xml" column without an XPath query. When you include a column that has been received from a previous component without an XPath query, it acts as a pass through. As shown below....

The screenshot shows the configuration for the tExtractXMLField\_1 component. The interface includes a top navigation bar with 'Job', 'Contexts(CommunityJobLoopingXML)', 'Component', 'Run (Job CommunityJobLoopingXML)', 'Test Cases', and 'Cloud Artifa'. The component name 'tExtractXMLField\_1' is displayed at the top left. A sidebar on the left contains menu items: 'Basic settings', 'Advanced settings', 'Dynamic settings', 'View', 'Documentation', and 'Validation Rules'. The main configuration area is divided into several sections:

- Property Type:** Built-In
- Schema:** Built-In, with 'Edit schema' and 'Sync columns' buttons.
- XML field:** xml
- Loop XPath query:** `"/HarvestedProduction/Machine"`
- Mapping:** A table with columns 'Column', 'XPath query', and 'Get Nodes'.

Column	XPath query	Get Nodes
xml		<input type="checkbox"/>
MachineKey	<code>"/MachineKey"</code>	
MachineUserID	<code>"/MachineUserID"</code>	
MachineApplicationVersion	<code>"/MachineApplicationVersion"</code>	
MachineBaseManufacturer	<code>"/MachineBaseManufacturer"</code>	
MachineBaseModel	<code>"/MachineBaseModel"</code>	
- Limit:** An empty text input field.
- Die on error:**

I won't show the tMap\_1 component. It simply sends the "Machine" columns to the "Machine" tHashOutput component and sends the "xml" column to other two outputs for further processing.

The next component is the tExtractXMLField\_2 component.

Job Contexts(CommunityJobLoopingXML) Component Run (Job CommunityJobLoopingXML) Test Cases Cloud Artifa

### tExtractXMLField\_2

**Basic settings**

Property Type: Built-In

Schema: Built-In Edit schema Sync columns

XML field: xml

Loop XPath query: `"/HarvestedProduction/Machine/SpeciesGroupDefinition"`

Mapping

Column	XPath query	<input type="checkbox"/> Get Nodes
SpeciesGroupDefinition	""	<input checked="" type="checkbox"/>
SpeciesGroupModificationDate	"/SpeciesGroupModificationDate"	<input type="checkbox"/>
SpeciesGroupName	"/SpeciesGroupName"	<input type="checkbox"/>

Limit

Die on error

This extracts every "SpeciesGroupDefinition" node (see the Get Nodes tickbox is ticked) and examples of its accompanying data. These are passed to the next component. The "SpeciesGroupDefinition" column is of type Document.

The next component is the tExtractXMLField\_3 component. We get the "StemTypeDefinition" data here. Its config can be seen below...

Job Contexts(CommunityJobLoopingXML) Component Run (Job CommunityJobLoopingXML) Test Cases Cloud Artifa

### tExtractXMLField\_3

**Basic settings**

Property Type: Built-In

Schema: Built-In Edit schema Sync columns

XML field: SpeciesGroupDefinition

Loop XPath query: `"/SpeciesGroupDefinition/StemTypeDefinition"`

Mapping

Column	XPath query	<input type="checkbox"/> Get Nodes
SpeciesGroupModificationDate		
SpeciesGroupName		
StemTypeCode	<code>"/StemTypeCode"</code>	
StemTypeName	<code>"/StemTypeName"</code>	

Limit

Die on error

Here we have a couple of pass-through columns (SpeciesGroupModificationDate and SpeciesGroupName) and we are retrieving the "StemTypeCode" and "StemTypeName" columns. The next component is the "SpeciesGroupDefinition" tHashOutput.

The next section is essentially a repeat of the above, but for the ProductDefinition data. The tExtractXMLField\_4 is configured as below....

Job Contexts(CommunityJobLoopingXML) Component Run (Job CommunityJobLoopingXML) Test Cases Cloud Artifa

### tExtractXMLField\_4

**Basic settings**

Property Type: Built-In

Schema: Built-In Edit schema Sync columns

XML field: xml

Loop XPath query: `"/HarvestedProduction/Machine/ProductDefinition"`

Mapping

Column	XPath query	<input type="checkbox"/> Get Nodes
ProductDefinition	""	
ProductKey	"/ProductKey"	
ProductName	"/ClassifiedProductDefinition/ProductName"	

Limit

Die on error

Notice the similarities between this and tExtractXMLField\_2.

The final XML component is the tExtractXMLField\_5. This retrieves the `"/ProductDefinition/ClassifiedProductDefinition/DiameterDefinition/DiameterClasses/DiameterClass"` data. This is configured as below....

Job Contexts(CommunityJobLoopingXML) Component Run (Job CommunityJobLoopingXML) Test Cases Cloud Artifa

### tExtractXMLField\_5

**Basic settings**

Property Type: Built-In

Schema: Built-In Edit schema Sync columns

XML field: ProductDefinition

Loop XPath query: `"/ProductDefinition/ClassifiedProductDefinition/DiameterDefinition/DiameterClasses/DiameterClass"`

Mapping

Column	XPath query	<input type="checkbox"/> Get Nodes
ProductKey		
ProductName		
DiameterClassLowerLimit	<code>"/DiameterClassLowerLimit"</code>	
DiameterClassName	<code>"/DiameterClassName"</code>	

Limit

Die on error

All of the data retrieved is being stored in tHashOutput components. To release it (or join it) you would need corresponding tHashInput components. The data I retrieved from your XML can be seen below....

#### Machine Data
